

RELEASE NOTES

Product	Snow Inventory Agent for Unix
Version	6.0.2
Release date	2018-12-12
Content	Corrections

CORRECTIONS

The following corrections have been implemented in Snow Inventory Agent for Unix 6.0.2:

- Solaris 11 uses two commands to retrieve information about software installed on a machine, one of which gathers data about legacy packages. The Unix Agent has been updated to mimic the operating system behavior, and now runs the legacy command in addition to the standard `pkg info` command, and collates the result to provide a more comprehensive inventory.
- The agent now includes additional error-handling to process filenames retrieved by the Solaris package manager. When the agent encounters filenames that include characters outside of the POSIX standard, it now completes processing and creates a valid snowpack file containing inventory data.
- SPARC64 processors are now being recognized correctly by the agent.
- Unix `file` commands executed by the agent that return more data than standard error is set to manage previously caused the agent to wait indefinitely. Additional error-handling has been added to the agent to prevent it from waiting in such scenarios.
- The version number for the Solaris 10 operating system is now inventoried correctly.
